How Valve Sense can detect leaking valves in steam generating processes to avoid economic losses and increase health and safety on site

Overview

Steam is used in most industrial steam power processes to generate electric current or heat. It is applied in a wide variety of industries such as energy production, pharmaceuticals and pulp and paper, just to name a few.

As an example, each steam line in an industrial plant contains at least one vent and drain valve to remove air and water. The drainage should avoid temperature differences and material stress inside the lines. Vent and drain valves need to be closed during operation to avoid the loss of steam (= energy loss) and ensure the efficient operation of steam boilers.

The problem today

A 1 mm sized leak in a single steam valve can cost € 2,400 per year and studies show that 5-10% of valves applied in industries are leaking. However, inspection of such valves during operation is a great challenge for employees due to the high temperature surfaces of up to 400-500° C. Therefore, companies often remove valves during maintenance cycles and test them on the test bench to ensure that they are tight. These are costly and time-consuming processes which cannot be carried out too often (remove, test, and re-install valves takes up to 2 days). As a result, companies lose steam in case valves are leaking, the risk of injury increases in case of hot steam leakage, too much time and money is spent on inefficient maintenance and very often companies replace intact valves due to wrong assumptions.

CASE STUDY STEAM PROCESSES

SENSEVEN

Senseven

has developed a new digital solution

“Valve Sense” based on acoustic emission.

It is a software guided inspection tool which can support companies in inspecting valves – e.g. vent and drain valves - during operation, avoid economic losses and increase the health and safety for employees on site.

CASE STUDY STEAM PROCESSES

We turn your Smartphone into an intelligent inspection device

SENSEVEN

Senseven has applied Valve Sense for a leading energy producer in Austria in steam generating processes

The result

15 valves have been inspected

1 valve which was expected to be leaking was actually tight

1 leaking valve was detected

Your Business Case

Minimize steam (= energy) losses

Reduce costly maintenance time

Reduce health & safety risks to employees

Stop replacing healthy valves
